

The link to the XML File of the test plan using ACTS: [here](#)

Task 1: Create a test plan

1. There are 12 combinations of tests for 2-way interactions.
2. Theoretically, there are 1152 combinations for the above parameters.

Suppose we have a table “CAR_BOOKING_SERVICE_MASTER” that contains all the information about the cars that we have in the workshop. Each of the cars has an ID number that we can call using our database management tool.

To see if we have the car or not, we can just use the query as simple as (just example):

```
SELECT * FROM CAR_BOOKING_SERVICE_MASTER WHERE CAR_TYPE  
= 'TRUCK' AND COLOR = 'LILAC' AND ...(and so on)
```

Task 2: Removing impossible test cases (adding constraints)

1. After adding the above constraints, I got 16 combinations of tests. Here's [the excel file](#). I also tried 3-way interactions for the test and got 41 combinations of tests. Here's [the excel file](#).
2. The result wasn't exactly like I would've expected, because I thought there would be lesser combinations of tests after adding constraints. I think this happened because the previous combination with the existing condition (before adding constraints), hadn't covered up all the conditions after adding the constraints. Thus made the system fulfills all the combinations.
3. After comparing the first list with the list after adding the constraints, I found that adding constraints doesn't necessarily mean reducing the combinations of

tests. Sometimes it can increase the number of combinations in order to fulfill all the conditions.

Task 3: Enforcing pairs (adding requirements)

1. Since the requirement states that “...**most of** our customers...”, not “...**all of** our customers”, I couldn’t find any solution for the “most of”. I’ve tried different kinds of constraints that led to the final most satisfied answer (at least for me) which is the “all of” kind of answer. The number of combinations of tests that I got is 13. The result occurred with only 2 options for CarType = “Truck” and Color = “Yellow”. There’s no other option for another color. Here’s [the excel file](#).
2. I don’t really understand the meaning of the question.  I did add the requirements to the app to be built.

Task 4: Adding parameters to see combinatorial growth

- After adding a parameter with only one value, there’s no additional pairwise tests.
- After adding one more value to the parameter, there’s still no additional pairwise tests.
- With 3 values in the additional parameter, the number of pairwise tests increased to 15.
- After adding a few parameters with a different number of values, I got that what affects the number of 2-way interaction tests most is **the number of values**, because 2-way interaction or X-way interaction corresponds to the X parameters which have the highest number of values in it.
